# **Exercises: Data Types and Variables**

Problems for exercises and homework for the "Programming Fundamentals" course @ SoftUni.

You can check your solutions here: <a href="https://judge.softuni.bg/Contests/206/Data-Types-and-Variables-Exercises">https://judge.softuni.bg/Contests/206/Data-Types-and-Variables-Exercises</a>.

# 1. Practice Integer Numbers

Create a new C# project and create a program that assigns integer values to variables. Be sure that each value is stored in the correct variable type (try to find the most suitable variable type in order to save memory). Finally, you need to print all variables to the console.

Input	Output
-100	-100
128	128
-3540	-3540
64876	64876
2147483648	2147483648
-1141583228	-1141583228
-1223372036854775808	-1223372036854775808

#### Hints

Follow the idea in the code below:

```
sbyte num1 = -100;
byte num2 = 128;
short num3 = -3540;
// TODO ...
Console.WriteLine(num1);
Console.WriteLine(num2);
Console.WriteLine(num3);
// TODO ...
```

# 2. Practice Floating Point Numbers

Create a new C# project and create a program that assigns floating point values to variables. Be sure that each value is stored in the correct variable type (try to find the most suitable variable type in order to save memory). Finally, you need to print all variables to the console.

Input	Output
3.141592653589793238	3.141592653589793238
1.60217657	1.60217657
7.8184261974584555216535342341	7.8184261974584555216535342341

#### Hints

Just like at the previous problem, declare several variables of appropriate floating-point data type, assign the above listed values and print them.

# 3. Practice Characters and Strings

Create a new C# project and create a program that assigns character and string values to variables. Be sure that each value is stored in the correct variable. Finally, you need to print all variables to the console.

Input	Output
Software University	Software University
B	B
y	y
e	e
I love programming	I love programming

### **Hints**

Like at the previous problem, declare variables of type **char** or **sting**, assign the above values and **print** them.

## 4. Variable in Hexadecimal Format

Write a program that reads a number in hexadecimal format (0x##) convert it to decimal format and prints it.

Input	Output
0xFE	254
0x37	55
0x10	16

#### **Hints**

Use Convert.ToInt32(string, 16).

## 5. Boolean Variable

Write a program that reads a string, converts it to Boolean variable and prints "Yes" if the variable is true and "No" if the variable is false.

Input	Output
True	Yes
False	No

#### Hints

Use Convert. ToBoolean(string).

# 6. Strings and Objects

Declare two string variables and assign them with "Hello" and "World". Declare an object variable and assign it with the concatenation of the first two variables (mind adding an interval between). Declare a third string variable and initialize it with the value of the object variable (you should perform type casting).

Input	Output
	Hello World
World	

Стр. 2 от 9

# 7. Exchange Variable Values

Declare two integer variables a and b and assign them with 5 and 10 and after that exchange their values by using some programming logic. Print the variable values before and after the exchange, as shown below:

Input	Output
5	Before:
10	a = 5
	b = 10
	After:
	a = 10
	b = 5

#### Hints

You may use a temporary variable to remember the old value of a, then assign the value of b to a, then assign the value of the temporary variable to **b**.

# 8. Employee Data

A marketing company wants to keep record of its employees. Each record would have the following characteristics:

- First name
- Last name
- Age (0...100)
- Gender (m or f)
- Personal ID number (e.g. 8306112507)
- Unique employee number (27560000...27569999)

Declare the variables needed to keep the information for a single employee using appropriate primitive data types. Use descriptive names. Print the data at the console.

Input	Output
Amanda	First name: Amanda
Jonson	Last name: Jonson
27	Age: 27
f	Gender: f
8306112507	Personal ID: 8306112507
27563571	Unique Employee number: 27563571

#### Hints

```
string firstName = "Amanda";
// TODO ...
int employeeNumber = 27563571;
Console.WriteLine(firstName);
// TODO ...
Console.WriteLine(employeeNumber);
```

# 9. Reverse Characters

Write a program to ask the user for **3 letters** and print them in **reversed order**.

## **Examples**

Input	Output
Α	СВА
В	
С	

Input	Output
х	zYx
Υ	
z	

Input	Output
G	ngG
g	
n	

### 10. Centuries to Nanoseconds

Write program to enter an integer number of **centuries** and convert it to **years**, **days**, **hours**, **minutes**, **seconds**, **milliseconds**, **microseconds**.

## **Examples**

Input	Output
1	1 centuries = 100 years = 36524 days = 876576 hours = 52594560 minutes = 3155673600 seconds = 31556736000000 milliseconds = 315567360000000000000000000000000000000000
5	5 centuries = 500 years = 182621 days = 4382904 hours = 262974240 minutes = 15778454400 seconds = 15778454400000 milliseconds = 15778454400000000000000000000000000000000

### **Hints**

• Use an appropriate data type for every data conversion. Beware of **overflows!** 

# 11. Convert Speed Units

Create a program to ask the user for a **distance (in meters)** and the time taken (as three numbers: hours, minutes, seconds), and **print the speed**, in meters per second, kilometers per hour and miles per hour.

Assume 1 mile = 1609 meters.

# Input

- On first line you receive distance in meters
- On second hours
- On third minutes
- On fourth seconds

# Output

Every number in the output should be precise up to 6 digits after the floating point

- On first line speed in meters per second (m/s)
- On second line speed in kilometers per hour (km/h)
- On third line speed in miles per hour (mph)

# **Examples**

Input	Output
1000	0.2732241
1	0.9836066
1	0.6113155

Input	Output
10000	8.130081
0	29.26829
20	18.19036

Input	Output
200000	26.66667
2	96
5	59.66439

0		30		0	

#### **Hints**

- Search in internet how to convert units.
- The type **double** is big enough for the calculations.

#### **Rectangle Properties 12.**

Create a program to calculate rectangle's perimeter, area and diagonal by given its width and height.

## **Examples**

Input	Output	
10	30	
5	50	
	11.1803398874989	

Input	nput Output	
22.1	64.6	
10.2	225.42	
	24.3402958075698	

#### Hints

Use Math.Sqrt() to calculate square root for calculating the diagonal ( $c^2 = a^2 + b^2$ ). See http://www.mathopenref.com/rectanglediagonals.html.

# 13. Vowel or Digit

Create a program to check if given symbol is digit, vowel or any other symbol.

## **Examples**

Input	Output
а	vowel

Input	Output
9	digit

Input	Output
g	other

# **Integer to Hex and Binary**

Create a program to convert a decimal number to hexadecimal and binary number and print it.

# **Examples**

Input	Output
10	Α
	1010

Input	Output
420	1A4
	110100100

Input	Output	
256	100	
	100000000	

#### Hints

Use <a href="Convert.ToString(number">Convert.ToString(number</a>, base) and <a href="string.ToUpper">string.ToUpper</a>().

#### **Fast Prime Checker - Refactor 15.**

You are given a program that checks if numbers in a given range [2...N] are prime. For each number is printed "{number} is prime -> {True or False}". The code however, is not very well written. Your job is to modify it in a way that is easy to read and understand.

#### Code

```
Sample Code
          = int.Parse(Console.ReadLine());
for (int DAVIDIM = 0; DAVIDIM <= Do ; DAVIDIM++)</pre>
    bool TowaLIE = true;
    for (int delio = 2; delio <= Math.Sqrt(DAVIDIM); delio++)</pre>
        if (DAVIDIM % delio == 0)
            TowaLIE = false;
            break;
        }
    Console.WriteLine($"{DAVIDIM} is prime -> {TowaLIE}");
```

# **Examples**

Input	Output		
5	2 -> True		
	3 -> True		
	4 -> False		
	5 -> True		

#### Hints

- Search how to check if a number is prime
- Rename all variables such as to be clear what is their role in the algorithm

#### \* Comparing Floats 16.

Write a program that safely compares floating-point numbers (double) with precision eps = 0.000001. Note that we cannot directly compare two floating-point numbers  $\bf a$  and  $\bf b$  by  $\bf a==\bf b$  because of the nature of the floating-point arithmetic. Therefore, we assume two numbers are equal if they are more closely to each other than some fixed constant eps. Examples:

Number a	Number b	Equal (with precision eps=0.000001)	Explanation
5.3	6.01	False	The difference of 0.71 is too big (> eps)
5.00000001	5.00000003	True	The difference 0.00000002 < eps
5.00000005	5.00000001	True	The difference 0.00000004 < eps
-0.0000007	0.0000007	True	The difference 0.00000077 < eps
-4.999999	-4.999998	False	Border case. The difference 0.000001 == eps. We consider the numbers are different.
4.999999	4.999998	False	Border case. The difference 0.000001 == eps. We consider the numbers are different.

#### **17. Print Part of the ASCII Table**

Find online more information about ASCII (American Standard Code for Information Interchange) and write a program that prints part of the ASCII table of characters at the console. On the first line of input you will receive the char index you should start with and on the second line - the index of the last character you should print.

Input	Output
60 65	<=>?@A
69 79	EFGHIJKLMNO
97 104	abcdefgh
40 55	()*+,/01234567

#### 18. \* Different Integers Size

Given an input integer, you must determine which primitive data types are capable of properly storing that input.

## Input

You receive N - integer which can be arbitrarily large or small

## **Output**

You must determine if the given primitives are capable of storing it. If yes, then print:

```
{N} can fit in:
 dataType
```

If there is more than one appropriate data type, print each one on its own line and order them by size (sbyte < byte < short < ushort < int < uint < long).

If the number cannot be stored in one of the four aforementioned primitives, print the line:

```
{N} can't fit in any type
```

# **Examples**

Input	Output
-150	-150 can fit in: * short * int * long

Input	Output	
150000	150000 can fit in: * int * uint * long	

Input	Output	
1500000000	1500000000 can fit in: * int * uint * long	

Input	Output
	21333333333333333333333333333333333333

### **Hints**

Use the **try** ... **catch** construction.

#### \* Thea the Photographer 19.

This problem is from the Programming Fundamentals Retake Exam (11 September 2016).

Thea is a photographer. She takes pictures of people on special events. She is a good friend and you want to help her.

She wants to inform her clients when their pictures will be ready. Since the number of pictures is big and it requires time for editing (#nofilter, #allnatural) every single picture - you decide to write a program in order to help her.

Thea follows this pattern: first she takes all pictures. Then she goes through every single picture to filter these pictures that are considered "good". Then she needs to upload every single filtered picture to her cloud. She is considered ready when all **filtered** pictures are **uploaded** in her picture storage.

You will receive the **amount** of pictures she had taken. Then the approximate **time** in **seconds** for every picture to be filtered. Then a filter factor – a percentage (integer number) of the total photos (rounded to the nearest bigger integer value e.g. 5.01 -> 6) that are good enough to be given to her clients (Photoshop may do miracles but Thea does not). Approximate time for every picture to be uploaded will be given again in seconds. Your task is: based on this input to display total time needed for her to be ready with the pictures in given below format.

## Input

On the first line you will receive an integer **N** – the amount of pictures Thea had taken.

On the second line you will receive an integer FT – the amount of time (filter time) in seconds that Thea will require to filter every single picture.

On the third line you will receive an integer FF - the filter factor or the percentage of the total pictures that are considered "good" to be uploaded.

On the fourth line you will receive an integer UT – the amount of time needed for every filtered picture to be uploaded to her storage.

The input will be in the described format, there is no need to check it explicitly.

# **Output**

Print the amount of time Thea will need in order to have her pictures ready to be sent to her client in given format:

d:HH:mm:ss

d - days needed - starting from 0.

HH - hours needed - from 00 to 24.

mm - minutes needed - from 00 to 59.

ss - minutes needed - from 00 to 59.

# **Constrains**

The amount of total pictures Thea will have taken is range [0 ... 1 000 000]

The seconds for both filtering and uploading will be in range [0 ... 100 000]

The filter factor will be an integer number between [0 ... 100].

# **Examples**

Input	Output	Comments
1000 1 50 1	0:00:25:00	Total pictures = 1 000, 50% of them are useful -> Filtered pictures = 500  Total pictures * filter time = 1000 s  Filtered pictures * upload time = 500 s  Total time = 1500 s
5342 2 82 3	0:06:37:07	Total pictures = 5342 - 82% of them are useful -> 4380.44-> 4381 filtered.
